

Hello, today I want to talk about my Python program called “Dulce Sabor Ice Cream Shop.”

This program is a simple system where a user can order ice cream. First, the program asks the user how many ice creams they want. The maximum number is five.

If the user writes a number bigger than five, the program says that the order is not allowed.

If the number is correct, the program asks the user to choose the flavor of each ice cream. The flavors are **vanilla, chocolate, and strawberry**.

The program counts how many ice creams there are for each flavor.

If the user writes a flavor that is not on the list, the program shows a message saying the flavor is not valid.

At the end, the program shows the final results with the number of vanilla, chocolate, and strawberry ice creams.

This program is a simple way to practice Python and learn how to count user choices in a program.

Thank you for your attention.
